Logistic Regression, Linear Classification and Stochastic Gradient Descent

Abstract—Logistic Regression is a method using regression techniques to achieve classification. Stochastic Gradient Descent is an advanced way to solve optimizing problems, and is very popular in the field of machine learning. This experiment combines these two.

I. INTRODUCTION

This report will talk about the whole experiment I have made on Logistic Regression and Linear classification, which are based on Stochastic Gradient Descent. Its content is organized as follow:

- 1) Section II contains the experiment steps.
- 2) Section III contains the code for the two experiments.
- 3) Section IV makes conclusion for the experiment result.

II. METHODS AND THEORY

Experiment uses a9a of LIBSVM Data, including 32561/16281(testing) samples and each sample has 123/123 (testing) features. Please download the training set and validation set.

Then the experiment will be performed by the following steps:

- 1) Download the dataset to local host machine.
- 2) Load dataset into memory.
- 3) Split dataset into training set and validation set.
- 4) Create and fill necessary data structures according to different optimizing methods.
- 5) Write functions for calculating loss and gradient (different in regression and classification).
- 6) Set parameters for different optimizing methods (learning rate and the number of iterations).
- 7) Initiate weights (using normal distribution).
- 8) Calculate the gradient and update weights according to the optimizing methods.

- 9) Switch to another optimizing method and run again.
- 10) Draw plot for experiment result.

III. EXPERIMENT

Here I placed the code for the two experiments:

1) Logistic Regression:

```

1. # created by Swain, 2017-12-14, 13:25
2.
3. import math
4. import numpy
5. import matplotlib.pyplot as plot
6. from numpy import random
7. from sklearn.datasets import
   load_svmlight_file
8.
9. #load a9a dataset
10. #training dataset
11. data = load_svmlight_file('./a9a')
12. X_train = data[0].toarray()
13. y_train = data[1]
14. data = load_svmlight_file('./a9a.t')
15. X_vali = data[0].toarray()
16. y_vali = data[1]

142.         hat_n = nt * (1/(1-beta2))
143.         W = W - hat_m *
(lr/(math.sqrt(hat_n)+epsilon))
144.
145.     names = ['NAG', 'RMSprop', 'AdaDelta',
'Adam']
146.     i = 0
147.
148.     plot.plot(loss_train[i], label="training loss")
149.     plot.plot(loss_val[i], label="validation loss")
150.     plot.legend()
151.     plot.xlabel("Iteration")
152.     plot.ylabel("Validation Loss")
153.     plot.title('Logistic Regression + ' +
names[i])
154.     plot.show()

```

2) Linear Classification:

The only difference from the former is the loss function and its corresponding gradient function.

```

1.  #define loss function (Hinge loss)
2.  def loss(X, W, y, _lambda):
3.      y_predict = numpy.dot(X,W)
4.      diff = numpy.ones(y.shape[0]) - y *
y_predict
5.      diff[diff < 0] = 0
6.      W_0 = W.copy()
7.      W_0[len(W) - 1] = 0
8.      return numpy.sum(diff) / X.shape[0] +
numpy.dot(W_0,W_0.T) / 2 * _lambda

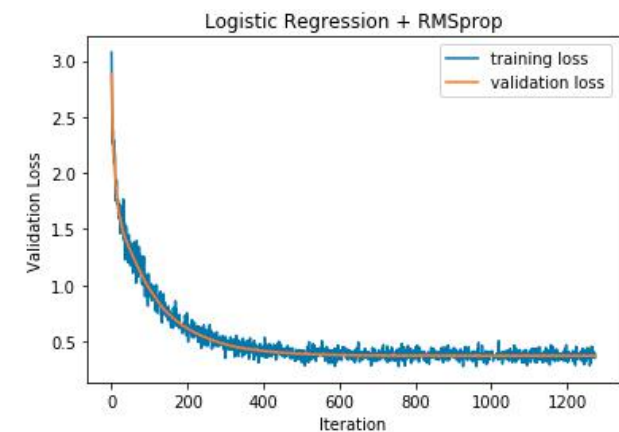

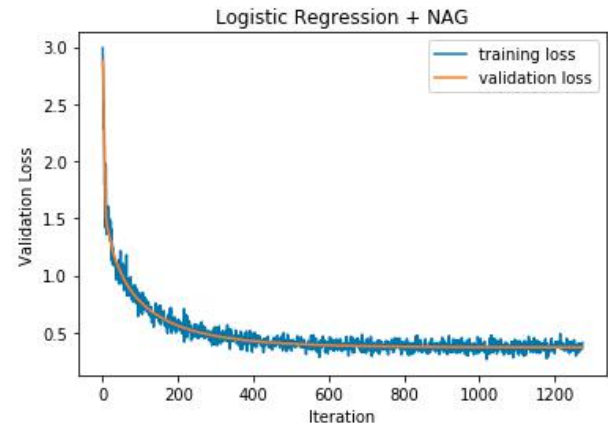

9.  #define gradient function
10. def grad(X, W, y, _lambda):
11.      y_predict = numpy.dot(X,W)
12.      diff = numpy.ones(y.shape[0]) - y *
y_predict
13.      y_ = y.copy()
14.      y_[diff <= 0] = 0
15.      W_0 = W.copy()
16.      W_0[len(W) - 1] = 0
17.      return -numpy.dot(y_,X) / X.shape[0] + W_0
* _lambda

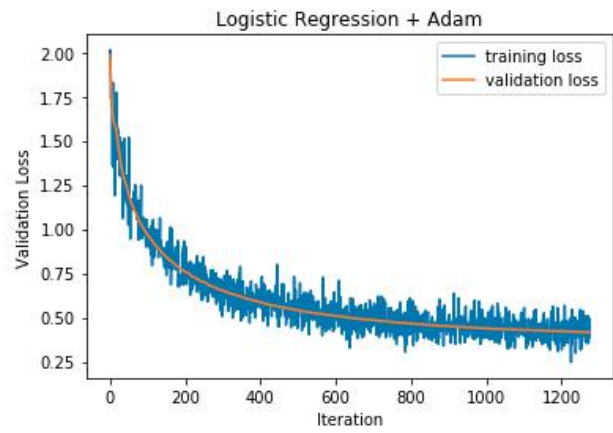

```

IV. CONCLUSION

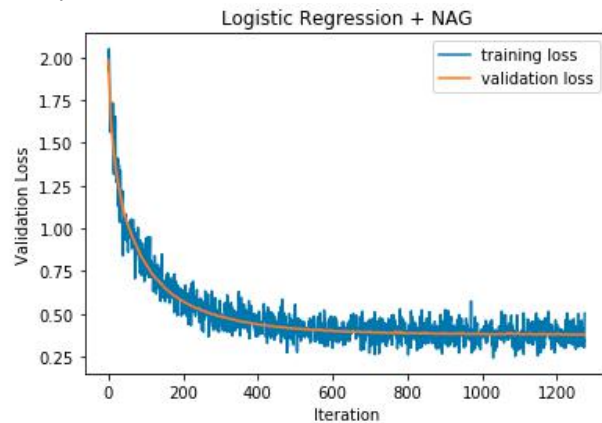

Here is the experiment result gained:

1) Logistic Regression

2) Linear Classification

Then we can draw a conclusion according to the two experiments:

- 1) Using batches to train the model is faster and more effective.
- 2) The 4 optimizing methods show slight ference on loss in these two experiments.
